## **Abstract**

The new carbon farming initiative (CFI) has raised a number of issues in regards to how producers may determine on-farm methane (CH<sub>4</sub>) and nitrous oxide (N<sub>2</sub>O) emissions. This project has modelled emissions of the green house gases (GHG) CH<sub>4</sub> and N<sub>2</sub>O from lamb production and evaluated a 'do now' emissions management strategy across 50 years of variable climate (1961-2011). A measure of emissions intensity (kg CO<sub>2</sub>e/kg live weight) of lamb production on the Northern Tablelands of Australia for low and high productivity landscapes has been evaluated. The Sustainable Grazing Systems (SGS) pasture model and GrassGro have been used to perform 50 year simulations and FarmGas, an inventory calculator, was used to calculate emissions over a 1 year period. Differences between packages in growth and emissions estimates exist. SGS, over 50 years, estimated 15,330 vs. 8,410 kg CO<sub>2</sub>e/year of enteric CH<sub>4</sub> emissions and 4.08 vs. 4.86 kg/kg emissions intensity for high and low productivity landscapes, respectively; and 10.39 vs. 3.42 t CO<sub>2</sub>e/ha/year of N<sub>2</sub>O for high and low productivity landscapes, respectively. GrassGro, over 50 years, estimated 24,154 vs. 11,510 kg CO<sub>2</sub>e/year of enteric CH<sub>4</sub> and 8.53 vs. 9.50 kg /kg emissions intensity for high and low productivity landscapes, respectively. FarmGas, over 1 year, estimated 20,823 vs. 10,229 kg CO<sub>2</sub>e/year of enteric CH<sub>4</sub> and 5.43 vs. 6.04 kg/kg emissions intensity for high and low productivity landscapes, respectively; and 3,267 vs. 1,584 kg CO<sub>2</sub>e/year of N<sub>2</sub>O for high and low productivity landscapes, respectively with a total intensity of 6.28 vs. 6.97 for high and low productivity landscapes, respectively. In conclusion, total emissions are higher for high productivity landscapes but in terms of intensity, high productivity landscapes produce less CH<sub>4</sub> per product produced on more highly productive landscapes. This finding was consistent across all emissions calculators used, but the magnitude of emissions and of emission intensities varied with the calculator used.

## **Executive summary**

This project developed a simulation of lamb production on the Northern Tablelands of Australia using: (1) the Sustainable Grazing Systems (SGS) pasture model ([www.imj.com.au/sgs](http://www.imj.com.au/sgs)); and (2) the GrassGro (Donnelly et al. 1998) decision support tool; and (3) A 1 year inventory of GHG using The FarmGas (Australia Farm Institute, 2010) inventory calculator. In each of the packages, where possible, the total amount of enteric methane (CH<sub>4</sub>) and nitrous oxide (N<sub>2</sub>O) has been estimated. In this study lamb live weight (LW) at point of sale (i.e. 24 weeks old) is used as the product produced. An emissions intensity [emissions per product produced (kg CO<sub>2</sub>e/kg LW)] is calculated for high and low productivity landscapes. Simulations were conducted over 50 years (01/09/1961 to 21/03/2010). Where appropriate the observed values collected from the Trevenna project (B.CHH.1033) have been compared to the predictions from the simulations.

## **Results**

### SGS

Mean lamb weights at 24 weeks of age over a 50 year simulation were estimated at 39.13 *versus* 36.02 kg for high and low productivity landscapes, respectively. Stock respiration (kg CO<sub>2</sub>e/year) (i.e. enteric CH<sub>4</sub>) was 15,330 vs. 8,410 for high and low productivity landscapes, respectively; and the emissions intensity was 4.08 vs. 4.86 kg CO<sub>2</sub>e/kg LW for high and low productivity landscapes, respectively. N<sub>2</sub>O was 10.39 vs. 3.42 t CO<sub>2</sub>e/ha/year for high and low productivity landscapes, respectively.

### GrassGro

Over a 50 year simulation mean wether lamb weights at 24 weeks of age were estimated at 31.10 vs. 26.73 kg for high and low productivity landscapes, respectively and ewe lamb weights at 24 weeks of age were estimated at 27.87 vs. 23.74 kg for high and low productivity landscapes, respectively. Total enteric CH<sub>4</sub> production was 24,154 vs. 11,510 kg CO<sub>2</sub>e/year for high and low productivity landscapes, respectively; and the emissions intensity was 8.53 vs. 9.50 kg CO<sub>2</sub>e/kg LW for high and low productivity landscapes, respectively.

### FarmGas

Total enteric CH<sub>4</sub> production was 20,823 vs. 10,229 kg CO<sub>2</sub>e/year for high and low productivity landscapes, respectively; and the emissions intensity 5.43 vs. 6.04 for high and low productivity landscapes, respectively. N<sub>2</sub>O emissions of 3,267 vs. 1,584 kg CO<sub>2</sub>e/year for high and low productivity landscapes, respectively. Total emissions intensity was therefore 6.28 vs. 6.97 kg CO<sub>2</sub>e/kg LW for high and low productivity landscapes, respectively.

## **Discussion on modelling**

The 3 packages (SGS, GrassGro, and FarmGas) all provide some important baseline figures for the Northern Tablelands of Australia. Differences between all packages did occur with GrassGro having the highest CH<sub>4</sub> estimates followed by FarmGas and then SGS. The GrassGro and FarmGas methods of estimating CH<sub>4</sub> are based on the Blaxter & Clapperton (1965) empirical equation and the SGS model is based on energy in CH<sub>4</sub> per gross energy intake of: forage 6% and concentrate 4%. Both methods rely heavily on intake and therefore if the models get intake wrong then subsequently the estimates will be wrong. As reported in B.CCH.1033 the observed values from the FTIR study were approx. 20 g CH<sub>4</sub>/head/day. The observed values therefore give some credence to the estimated values from the packages. All 3 packages can be used to estimate CH<sub>4</sub> production provided good input data is supplied. Both SGS and FarmGas report N<sub>2</sub>O emissions but it is difficult to determine the accuracy of estimated N<sub>2</sub>O and further data collection of N<sub>2</sub>O is required before solid comparisons can be made.

## **Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

### ***Conclusions***

A 'do now' management strategy of improving pasture productivity, simulated across 50 years of variable climate, can reduce the amount of CH<sub>4</sub> emitted per unit of lamb produced. The Trevenna project (B.CCH.1033) demonstrated this 'do now' management strategy over a 2 year period. Both the SGS and GrassGro 50 year simulations demonstrated that emissions intensity of lamb from high productivity landscapes is less than from low productivity landscapes. However, variation in estimates of total CH<sub>4</sub> emissions and of live weight of lambs occurred between simulations. The FarmGas calculations of total CH<sub>4</sub> emissions were similar to the GrassGro results. Differences in total CH<sub>4</sub> emissions between these 2 simulation packages and the FarmGas inventory calculator need to be evaluated. The differences in total enteric CH<sub>4</sub> in the simulations may be attributed to the methods of calculating enteric CH<sub>4</sub> (Table 8 footnote and Table 9 footnote).

The average observed lamb LW for the flocks ranged from 33 to 40 kg and 39 to 45 kg on the 4<sup>th</sup> April 2011 for low and high productivity landscapes. When simulated over 50 years it would be expected that the average over 50 years would be lower than the observed values in 2011 due to the excellent season in 2011. GrassGro results as mentioned above were lower than the SGS results.

Each package used in this study is quite different and the question the user is addressing will ultimately determine which package should be used. Techniques to measure CH<sub>4</sub> and N<sub>2</sub>O in the paddock are still under development therefore actual estimates of CH<sub>4</sub> and N<sub>2</sub>O are highly variable. Hence, when actual measurements are scarce, estimates of CH<sub>4</sub> and N<sub>2</sub>O from the 3 packages can provide some important baseline figures for the Northern Tablelands of Australia.

Knowledge has been gained through the simulations and inventory calculation: (1) in terms of how much enteric CH<sub>4</sub> is emitted; (2) the variability between packages; and (3) consistency of the emission intensity result when simulated across 50 years.

### ***Recommendations***

The SGS package is highly suitable for research scientists to gain insight into animal production systems and GrassGro is a valuable tool that can assist livestock officers make management decisions. The differences in the prediction of lamb live weights in SGS and GrassGro need further investigation. This study demonstrated a 'do now' management strategy and the data validated against observed data (01/09/2010 to 21/03/2011) provides a valuable data set that could be used in future simulation studies to test carbon farming initiative (CFI) methodologies. Significant improvements have already been made in predicting pasture species on the Northern Tablelands but further developments are required.

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Background

There is considerable interest nationally and internationally in reducing methane emissions from livestock. A practical demonstration of methane management strategies (B.CCH.1033) for the sheep industry was established at the University of New England (UNE) field site, Trevenna, Armidale, NSW. Project B.CCH.1033 collected data on green house gases (GHG) (CH<sub>4</sub>, N<sub>2</sub>O and CO<sub>2</sub> fluxes) for both low and high productivity sheep production systems and demonstrated at field days the technologies used to estimate methane (e.g. FTIR, SF<sub>6</sub> canisters, and estimates of CH<sub>4</sub> from decision support tools (e.g. GrazFeed, GrasGro, SGS, and FarmGas)) and the intensity of production (CH<sub>4</sub>/unit of production). In addition to GHG, soil composition, pasture biomass (green and dead), botanical composition and production data were collected.

### Project objectives

Use the data collected from the Trevenna sheep production demonstration site (B.CCH.1033) to:

- 1) Simulate over 50 years the pasture and sheep production system on the Northern Tablelands and compare actual measured values with simulated values where available using:
  - GrassGro (CSIRO), and
  - SGS (IMJ consultants)
- 2) Calculate inventory C budgets using:
  - FarmGas (Australian farm C budget model. Farm institute site), and

Outcomes:

- A study comparing the estimates of CH<sub>4</sub> as CO<sub>2</sub> equivalents (CO<sub>2</sub>e) using GrassGro and SGS.
- Estimates of CH<sub>4</sub> (CO<sub>2</sub>e) and N<sub>2</sub>O (CO<sub>2</sub>e) using FarmGas.

### Methodology

A 36-hectare demonstration site at Trevenna, University of New England, Armidale on the Northern Tablelands of New South Wales was established to give livestock producers a practical insight into the magnitude of carbon fluxes, especially methane (CH<sub>4</sub>), associated with crossbred lamb production. A replicated study over two years was established to compare animal productivity and emissions of low (3.7 DSE/ha) and high (6.7 DSE/ha) productivity landscapes. Data collected (soil, pasture, sheep production, and GHG) from the 1<sup>st</sup> year (10th Sept 2010– 4<sup>th</sup> April 2011) has been used to enter initial values into the simulation packages (SGS and GrassGro) and challenge simulated values with observed values i.e., ground truth the package so that producers and research scientists can gain confidence in the results from the simulation. The FarmGas calculator is a static calculation over a specified period and is easier to use than the simulation packages. Again the data collected from the Trevenna site (B.CCH.1033) was used to perform the FarmGas calculations. The results from SGS and GrassGro over a 50 year simulation and the results from FarmGas over 1 year were used to estimate total on-farm CH<sub>4</sub> emissions and the intensity of emissions per unit product. The unit of product in this study is lamb live weight at time of sale.

### Methods

#### Trevenna Demonstration Site

The Trevenna demonstration site, located at the University of New England, on the Northern Tablelands of New South Wales (30° 30'S 151° 40' E) comprises 36 ha, split between high and low productivity systems. An overview of the site has been described by McPhee et al. (2010). The 'Trevenna' demonstration site has been subdivided into 18 paddocks: 9 allocated for high productivity improved pastures and 9 allocated for low productivity

## **Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

predominately native pastures. The paddocks averaged 2ha ranging from 1.8-2.2 ha. Each landscape was classified into classes (A, B and C) based on an EM38 electromagnetic induction survey. Within each class 3 paddocks were allocated. There were 6 flocks: 3 high and 3 low productivity flocks. Flocks were rotationally grazed through 3 paddocks so that each flock had a turn in each landscape class (A, B and C). The high productivity flocks were stocked at 6.7 DSE/ha (i.e. 32 ewes and single lambs rotationally grazing 6ha) and the low productivity flocks were stocked at 3.7 DSE/ha (i.e. 16 ewes and single lambs rotationally grazing 6ha).

### Data Collection

Data was collected to feed into the GrassGro and SGS decision support systems to estimate the amount of methane produced. Data collected was also used as inputs to the FarmGas (2010) greenhouse inventory calculator. The measurements taken include:

- Soil moisture measurements taken on a weekly basis. Measurements were taken using a Diviner moisture probe (Sentek Technologies, Sydney). The moisture probe used was a capacitance probe that uses the electrical conductivity of a soil to determine the moisture content (Thomas, 1966). The access tubes were located within one paddock of each land class within each landscape. The measurements were taken in 10cm increments to a depth of 50cm.
- Herbage mass measurements were undertaken on a monthly basis when the animals were rotated between paddocks. Pre and post grazing measurements were undertaken using the median quadrat technique (Bell, 2007). A scan of each quadrat was taken using a Crop Circle (Holland Scientific equipment model ACS210) scanner. The data from the observed values and the scans have been used to develop a Normalised Difference Vegetation Index (Trotter et al., 2010)
- Botanical compositions were conducted 4 times per year, once per season using the method described by Tothill et al. (1992).
- Lambs were weighed on a monthly basis, when mobs were rotated between paddocks. These monthly lamb weights were recorded using their National Livestock Identification System Radio Frequency Identification tag. Condition score, fleece weights, and quality of fleece were also recorded.

### SGS

The SGS model (Johnson, 2003) was used to perform a 50 year simulation of high and low productivity sheep production systems. The soil parameters in the SGS model were stabilised over a 10 year period from 1960 to 1970 before a full 50 year simulation from 1960-2010 was conducted. Each of the 2 landscapes was modelled separately for 3 flocks on each landscape that was rotational grazed across 3 paddocks from 1<sup>st</sup> September to 10<sup>th</sup> April (Tables 1 to 4) and in 5 paddocks during winter (Tables 2 and 4) using the information recorded from the Trevenna site (McPhee et al., 2010; B.CCH.1033). Data used from the site included: herbage mass, species composition and stocking density. Tables 1 to 5 were used to set up the simulation and a sigmoidal animal growth curve was selected.

Within the SGS model supplementary feeding was established to begin feeding when ewes dropped below 40kg liveweight. Below this weight forage and concentrate supplements were fed at a rate calculated by the model to produce liveweight gains. The implementation of supplementary feeding within the SGS model occurred when the pasture quantity and quality was insufficient to maintain liveweight. Actual on-farm supplementary feeding was supplied to ewes as per the UNE animal ethics requirements.

## **Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

The simulation was run using historical weather data for Armidale Airport Automatic Weather Station, NSW (30.5°S 151.6°E) (BOM, 2011). The initial pasture availability at the beginning of September 2010 was used as the starting herbage mass 1st September, 1960. The botanical composition assessment conducted in September was used as inputs to the SGS model. The soil nutrients and water values were used from the normalised values obtained in the 10 year scenario (1960-1970). Following the simulation the data produced was processed using the statistical package R. To ensure accuracy of the model the baseline simulation was run from the 1st September 2010 through to the 31<sup>st</sup> of March 2011. This enabled the predicted values from the simulation to be compared to the observed values of herbage mass, botanical composition, soil moisture and lamb weights.

### GrassGro

The GrassGro decision support system was used to perform a 50 year simulation of high and low productivity sheep production systems. Parameter values were stabilised during the acceptability run over 50 years from 1960-2011. Each of the 2 landscapes were modelled separately based on 1 flock on low productivity (ewes n=48) and high productivity (ewes n=96) landscape that were rotational grazed across 3 paddocks from 1<sup>st</sup> September to 10<sup>th</sup> April (Tables 1 to 3; and Table 5) and in 1 paddock during winter (Tables 2 and 4) using the information available from the Trevenna site (B.CCH.1033). The GrassGro simulation was based on a notional stocking rate of 2 ewes and 1 ewe/ha for high and low productivity landscapes, respectively; the total number of hectares for each landscape was 48 ha (i.e. the winter paddock was adjusted so that the total area was 48 ha for each landscape). The observed data over a 9 month simulation was used to check that the simulated values were a reasonably good fit. Full details of inputs are provided in Appendix 1. The CH<sub>4</sub> production/year was calculated in excel that used the mean CH<sub>4</sub> output per ewe and lamb over the 50 year simulation for each landscape.

### FarmGas

FarmGas was used to calculate an estimate of methane and N<sub>2</sub>O output. Seasonal averages were taken (e.g. weights of ewes and lambs across seasons; Note: seasonal values for pasture availability were also entered based off the estimated total and green pasture availability reported in Tables 17 to 32) and entered into FarmGas

### Units

The units used in this study are CO<sub>2</sub>e: 1 g CH<sub>4</sub> ~ 21 g CO<sub>2</sub>e; and 1 g N<sub>2</sub>O ~ 310 g CO<sub>2</sub>e. Note: authors acknowledge that these figures have changed i.e. 1 g CH<sub>4</sub> ~ 25 g CO<sub>2</sub>e is the new CO<sub>2</sub>e but results in this study are based on the old CO<sub>2</sub>e.

### Measure of intensity

The measure of intensity in this study is derived as kg CO<sub>2</sub>e per kg LW.

## **Results**

### SGS

The production data results are given in Table 7. Mean lamb weights over a 50 year simulation were estimated at 39.13 *versus* 36.02 kg for high and low productivity landscapes, respectively. GHG emissions are reported in Table 8. Enteric CH<sub>4</sub> (kg CO<sub>2</sub>e/year) was 15,330 vs. 8,410 for high and low productivity landscapes, respectively; and the lamb intensity 4.08 vs. 4.86 for high and low productivity landscapes, respectively.

### GrassGro

The production data and GHG emission results are given in Table 9. Over a 50 year simulation mean wether lamb weights were estimated at 31.10 *versus* 26.73 kg for high and

## **Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

low productivity landscapes, respectively and ewe lamb weights were estimated at 27.87 *versus* 23.74 kg for high and low productivity landscapes, respectively. Total enteric CH<sub>4</sub> production (calculated as shown in Table 10; reported in Table 9) was 24,154 vs. 11,510 kg CO<sub>2</sub>e/year for high and low productivity landscapes, respectively; and the lamb intensity 8.53 vs. 9.50 for high and low productivity landscapes, respectively.

### FarmGas

The CH<sub>4</sub> and N<sub>2</sub>O values calculated in FarmGas are reported in Table 12. Total enteric CH<sub>4</sub> production (Table 12) was 20,823 vs. 10,229 kg CO<sub>2</sub>e/year for high and low productivity landscapes, respectively; and the lamb intensity 5.43 vs. 6.04 for high and low productivity landscapes, respectively. N<sub>2</sub>O emissions of 3,267 vs. 1,584 kg CO<sub>2</sub>e/year for high and low productivity landscapes, respectively. Total intensity was therefore 6.28 vs. 6.97 for high and low productivity landscapes, respectively.

N <sub>2</sub> O emission: (kgN/ha/year)	21.32 (7.21)	7.03 (3.07)
N <sub>2</sub> O emission: (tCO <sub>2</sub> e/ha/year) <sup>1</sup>	10.39 (3.51)	3.43 (1.49)
Stock CO <sub>2</sub> respiration: (tC/ha/year)	9.83 (0.68)	5.08 (0.31)
Stock CO <sub>2</sub> respiration: (tCO <sub>2</sub> e/ha/year)	36.06 (2.46)	18.63 (1.13)
Stock CH <sub>4</sub> respiration: (tC/ha/year)	0.55 (0.04)	0.28 (0.02)
Stock CH <sub>4</sub> respiration: (kg CO <sub>2</sub> e/year) <sup>2</sup>	<b>15,330</b> (1.06)	<b>8,410</b> (0.54)
Emissions intensity <sup>3</sup> (kg CO <sub>2</sub> e/kg LW)	<b>4.08</b> (-)	<b>4.86</b> (-)

1. Observed values in Autumn = 1.49 and 0.37 kg CO<sub>2</sub>e/ha/day on high and low productivity landscapes, respectively in Autumn; 0.97 kg and 0.074 kg CO<sub>2</sub>e/ha/day on high and low productivity landscapes, respectively in Winter (See BCCH 1033 report for more detail). Based on 310 CO<sub>2</sub>e = 1 g N<sub>2</sub>O.
2. Equates to calculations based on energy in CH<sub>4</sub> per gross energy intake of; forage 6%; concentrate 4%; equates to 19.89 and 13.26 g CH<sub>4</sub> (kg d.wt intake)<sup>-1</sup>. Based on 1 g CH<sub>4</sub> ~ 21 g CO<sub>2</sub>e
3. Intensity calculated as total stock CH<sub>4</sub> respiration/(no lambs x lamb wts given in Table 7 above).

**Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

**Table 9.** Mean values of production data and GHG emissions over a 50 year GrassGro simulation for high and low productivity landscapes; mean ( $\pm$ SD)

	<b>High Productivity</b>	<b>Low Productivity</b>
Methane production main flock <sup>1</sup> (g/head/d)	24.52 (3.98)	23.86 (3.53)
Methane production Young sheep (g/head/d)	16.43 (10.43)	14.68 (9.34)
Feed budget (Animal intake) <sup>2</sup> (kg/head/d)	1.34 (0.97)	1.18 (0.37)
Total ME intake (MJ/head)	10.44 (2.58)	9.93 (2.16)
Available herbage <sup>3</sup> (Green DM (P1)) (kg/ha)	2288.13 (946.95)	1002.50 (369.75)
Available herbage <sup>3</sup> (Dead+Litter (P1)) (kg/ha)	4193.02 (900.49)	1732.81 (358.35)
Digestibility <sup>3</sup> (Green (P1)) (%)	56.48 (4.93)	58.28 (5.57)
Total animal methane <sup>4</sup> (kg CO <sub>2</sub> e/year)	<b>24,154</b> (-)	<b>11,510</b> (-)
Sale weight (Wether Lambs) (kg)	<b>31.10</b> (-)	<b>26.73</b> (-)
Sale weight (Ewe Lambs) (kg)	<b>27.87</b> (-)	<b>23.74</b> (-)
Lamb intensity <sup>5</sup> (kg CO <sub>2</sub> e/kg LW)	<b>8.53</b> (-)	<b>9.50</b> (-)

1. Estimate of methane based on Blaxter & Clapperton (1965 ) empirical equation
2. Notational stocking rate = 2 and 1/ha for high and low productivity landscapes, respectively, with 48ha total area across all paddocks for each landscape.
3. Only 1 of 4 paddocks reported
4. Total stock methane ((kg CO<sub>2</sub>e/year) was calculated using the methane production values of main flock and young sheep reported in this table. A spread sheet calculated values for 3 within landscape classes and a winter paddock fro each landscape; total area = 48 ha (See Table 10)
5. Intensity calculated as total animal methane/[no lambs x (avg of wether and lamb wts)]. Note total animal methane = no of ewes x CH<sub>4</sub> output of ewes + no. lambs x CH<sub>4</sub> output of lambs.

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

**Table 10.** Excel calculations for calculating total (T) stock methane emissions in kg CO<sub>2</sub>e across landscapes (LS) (low and high productivity) within landscape classes (A,B, and C) and during autumn/winter (W) grazing, for ewe (E) and lamb (L) numbers based off mean methane output (g/head) simulated over 50 years in GrassGro

### Acceptability report - All flocks of Ewes @ Trevenna Low Prod

1/09/1961 - 21/03/2011

Mean annual rainfall for years tested

Mean annual rainfall [1 Jan - 31 Dec, 1962-2010]

Date	Rainfall (sum) (mm)
-	766

### Annual rainfall by years

Total annual rainfall [1/09/1961 - 21/03/2011]

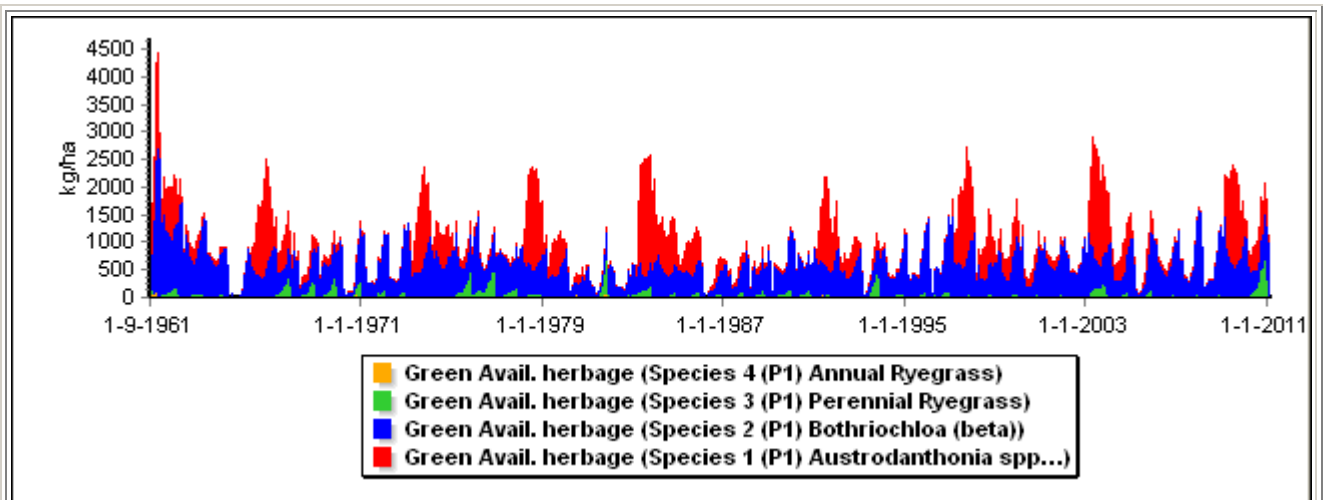

### Production over years

#### Pasture composition by years - Paddock 1

Green available herbage by species [1/09/1961 - 21/03/2011]

**Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

Pasture composition by years - Paddock 2  
Green available herbage by species [1/09/1961 - 21/03/2011]

Pasture composition by years - Paddock 3  
Green available herbage by species [1/09/1961 - 21/03/2011]

Pasture availability by years - Paddock 1  
Available green and (dead + litter) herbage [1/09/1961 - 21/03/2011]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Pasture availability by years - Paddock 2

Available green and (dead + litter) herbage [1/09/1961 - 21/03/2011]

Pasture availability by years - Paddock 3

Available green and (dead + litter) herbage [1/09/1961 - 21/03/2011]

---

### Numbers of sheep in the main flock

Number of animals present (head) [1/09/1961 - 21/03/2011]

**Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

**Numbers of young sheep**

Number of animals present (head) [1/09/1961 - 21/03/2011]

**Lamb mortality**

Number of lambs per ewe and the mortality rate at birth [8 Sep - 12 Sep, 1961-2010]

**Live weight of female sheep in the main flock**

Live weight of each class (kg/head) [1/09/1961 - 21/03/2011]

**Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

Live weight of young sheep  
Live weight (kg/head) [1/09/1961 - 21/03/2011]

Fleece weight shorn each year for sheep in the main flock  
Clean fleece weight shorn (kg/head) [1 Jan - 31 Dec, 1962-2010]

Fleece weight shorn each year for young sheep  
Clean fleece weight shorn (kg/head) [9 Jul - 10 Jul, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Average annual wool production of age classes in the main flock

Long term average annual clean fleece weight (kg/head) and fleece fibre diameter (micron) [1 Jan - 31 Dec, 1962-2010]

Date	CFW -main flock						Fleece fibre diameter				
	Female weaners (max) (kg/head)	Female 1-2 y.o. (max) (kg/head)	Female mature (max) (kg/head)	Male weaners (max) (kg/head)	Male 1-2 y.o. (max) (kg/head)	Male mature (max) (kg/head)	Female weaners (av.) (microns)	Female 1-2 y.o. (av.) (microns)	Female mature (av.) (microns)	Male weaners (av.) (microns)	Male 1-2 y.o. (av.) (microns)
-	n/a	2.77	2.73	n/a	n/a	n/a	n/a	17.3	17.3	n/a	n/a

### Average wool production of young sheep

Long term average clean fleece weight (kg/head) and fleece fibre diameter (micron) [9 Jul - 10 Jul, 1962-2010]

Date	CFW -young sheep					Fleece fibre diameter				
	Unweaned (max) (kg/head)	Male weaners (max) (kg/head)	Male yearlings (max) (kg/head)	Female weaners (max) (kg/head)	Female yearlings (max) (kg/head)	Unweaned (av.) (microns)	Male weaners (av.) (microns)	Male yearlings (av.) (microns)	Female weaners (av.) (microns)	Female yearlings (av.) (microns)
-	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a

### Supplement intake of sheep in the main flock

Total monthly supplement intake (kg DM/head) [1/09/1961 - 21/03/2011]

### Supplement intake of all young sheep

Total monthly supplement intake for all young sheep (kg DM/head) [1/09/1961 - 21/03/2011]

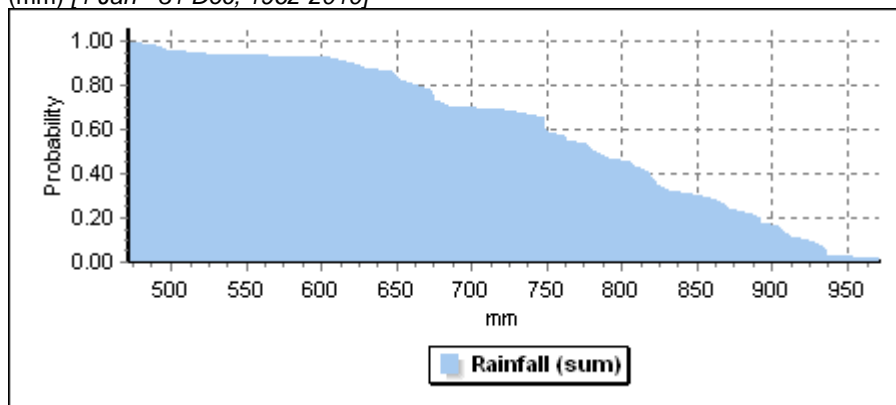

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Variability of the whole farm system

#### Distribution of annual rainfall

The probability (shown on the vertical axis) of annual rainfall exceeding the value shown on the horizontal axis (mm) [1 Jan - 31 Dec, 1962-2010]

#### Distribution of growing season rainfall

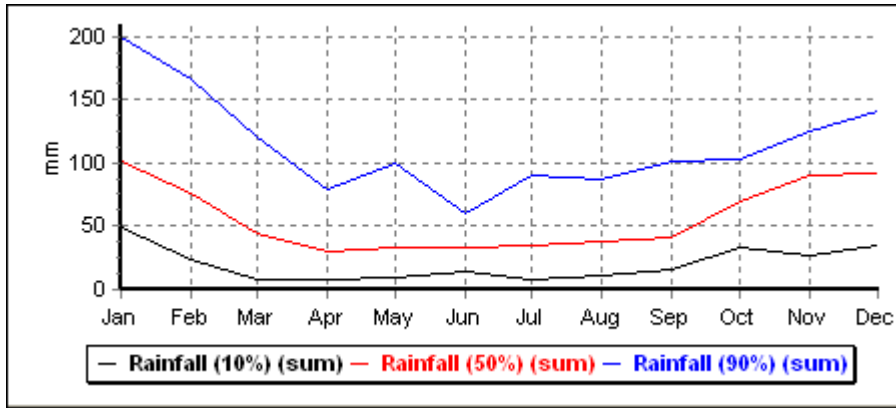

The probability of rainfall between 1 Apr and 31 Oct exceeding the value shown on the horizontal axis (mm) [1 Apr - 31 Oct, 1962-2010]

#### Monthly rainfall

Percentiles for monthly rainfall [1 Jan - 31 Dec, 1962-2010]

# Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

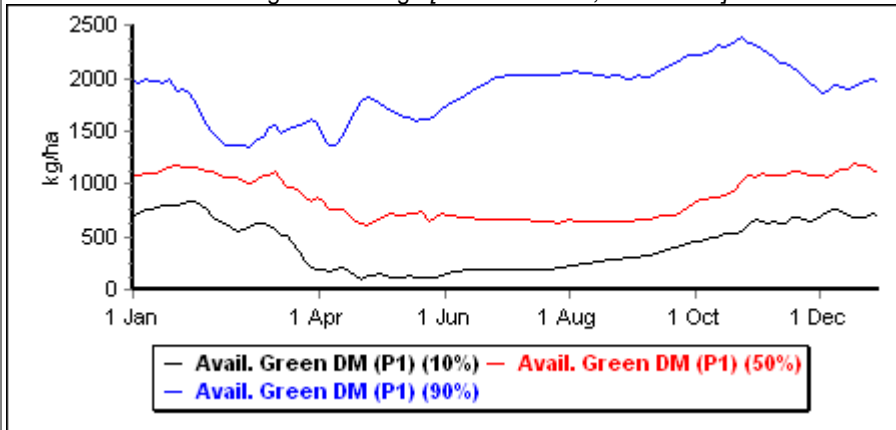

## Temperature

Long term average of monthly average maximum and minimum air temperature [1 Jan - 31 Dec, 1962-2010]

## Pasture supply - green - Paddock 1

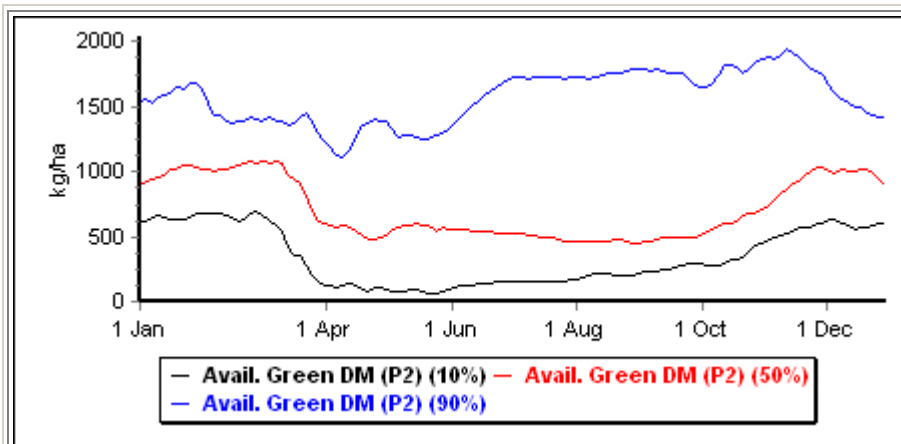

Percentiles for available green herbage [1 Jan - 31 Dec, 1962-2010]

## Pasture supply - green - Paddock 2

Percentiles for available green herbage [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Pasture supply - green - Paddock 3

Percentiles for available green herbage [1 Jan - 31 Dec, 1962-2010]

Average pasture composition - Paddock 1

Long term average green available herbage by species [1 Jan - 31 Dec, 1962-2010]

Average pasture composition - Paddock 2

Long term average green available herbage by species [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Average pasture composition - Paddock 3

Long term average green available herbage by species [1 Jan - 31 Dec, 1962-2010]

### Variability in live weight of mature female sheep in the main flock

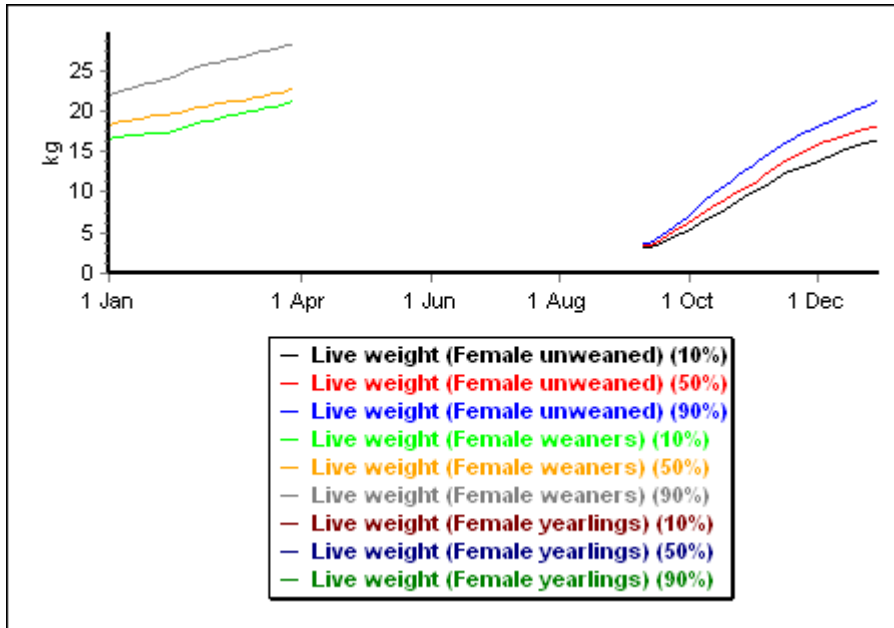

Percentiles for live weight, including fleece (kg/head) [1 Jan - 31 Dec, 1962-2010]

### Variability in live weight of ewe lambs

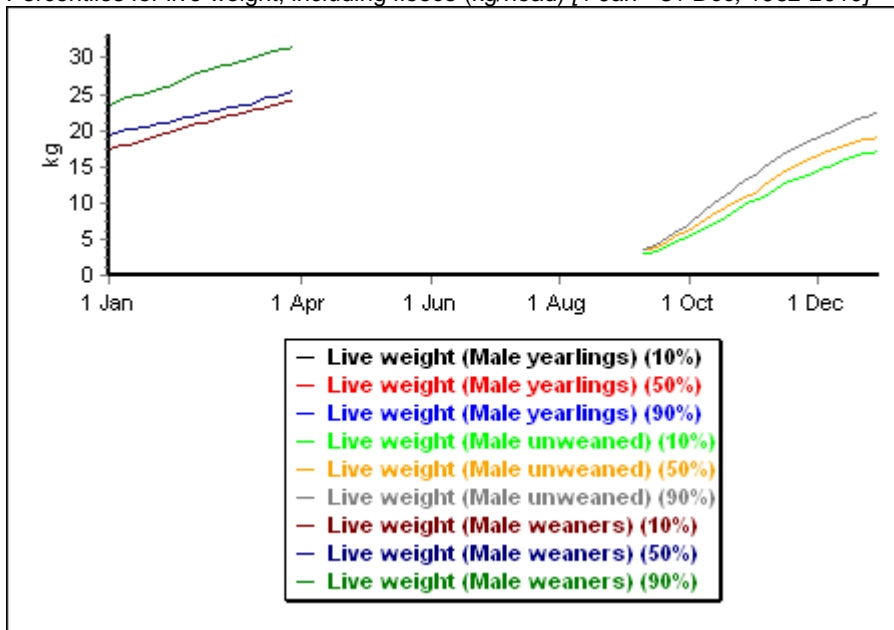

Percentiles for live weight, including fleece (kg/head) [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Variability in live weight of wether lambs

Percentiles for live weight, including fleece (kg/head) [1 Jan - 31 Dec, 1962-2010]

### Variability in body condition of mature female sheep in the main flock

Percentiles for body condition score [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Variability in body condition of ewe lambs

Percentiles for body condition score [1 Jan - 31 Dec, 1962-2010]

### Variability in body condition of wether lambs

Percentiles for body condition score [1 Jan - 31 Dec, 1962-2010]

### Variability in fibre diameter of mature female sheep in the main flock

Percentiles for fibre diameter (micron) [1 Jan - 31 Dec, 1962-2010]

**Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

Variability in fibre diameter of 1-2 year old sheep in the main flock  
 Percentiles for fibre diameter (micron) [1 Jan - 31 Dec, 1962-2010]

Variability in fibre diameter of young wethers (unweaned and weaned)  
 Percentiles for fibre diameter (micron) [1 Jan - 31 Dec, 1962-2010]

# Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

## Lambs per ewe

Percentiles for lambs per ewe [1 Jan - 31 Dec, 1962-2010]

## Variability in intake of maintenance and production supplement of the main flock

Percentiles for daily supplement intake (kg DM/head/d) [1 Jan - 31 Dec, 1962-2010]

## Variability in intake of maintenance and production supplement of young sheep

Percentiles for total daily supplement intake of young sheep (kg DM/head/d) [1 Jan - 31 Dec, 1962-2010]

## Variability in average daily gain (ADG) of wether lambs

Percentiles for average daily live weight gain -not fleece (kg/head/d) [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Pasture quality

#### Average quality of all herbage in each paddock

Long term average pasture dry matter digestibility (%) [1 Jan - 31 Dec, 1962-2010]

#### Average quality of green herbage for each paddock

Long term average pasture dry matter digestibility (%) [1 Jan - 31 Dec, 1962-2010]

#### Average quality of dead herbage and litter for each paddock

Long term average pasture dry matter digestibility (%) [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Variability in pasture growth rate - Paddock 1

Percentiles for average weekly pasture growth rate (kg DM/ha/d) [1 Jan - 31 Dec, 1962-2010]

### Variability in pasture growth rate - Paddock 2

Percentiles for average weekly pasture growth rate (kg DM/ha/d) [1 Jan - 31 Dec, 1962-2010]

### Variability in pasture growth rate - Paddock 3

Percentiles for average weekly pasture growth rate (kg DM/ha/d) [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Pasture growth rates for each paddock

Long term average pasture growth rates [1 Jan - 31 Dec, 1962-2010]

### Table of average monthly pasture and sheep growth rates

Long term average pasture and sheep growth rates, averaged over each month [1 Jan - 31 Dec, 1962-2010]

Date	Pasture growth			Weight change (Unweaned) (av.) (kg/d)	Weight change (Male weaners) (av.) (kg/d)	Weight change (Female weaners) (av.) (kg/d)	Weight change (Main mob)					
	P1 (av.) (kg/ha/d)	P2 (av.) (kg/ha/d)	P3 (av.) (kg/ha/d)				Female weaners (av.) (kg/d)	Female 1-2 y.o. (av.) (kg/d)	Female mature (av.) (kg/d)	Male weaners (av.) (kg/d)	Male 1-2 y.o. (av.) (kg/d)	Male mature (av.) (kg/d)

Feed budget

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Long term average daily pasture growth and intake of pasture by the whole enterprise (kg DM/ha/d) [1 Jan - 31 Dec, 1962-2010]

### Pasture utilization rate

The long term average amount of pasture consumed by all stock as a proportion of the amount of pasture grown over the period tested (%) [21 Mar - 21 Mar, 2011-2011]

Date	Utilization rate
	(%)
21 Mar	7

## Economics

### Production summary

Long term average pasture and sheep production. For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

Farm System		All flocks of Ewes @ Trevenna Low Prod
<b>Total annual pasture yield (NPP) (sum)</b>	kg/ha	6217
<b>Dry sheep equivalents (av.)</b>	dse/ha	1.5
<b>Wool cut - total flock (sum)</b>	kg CFW/ha	3
<b>Wool cut - lambs (sum)</b>	kg CFW/ha	0
<b>Shorn fibre diameter - ewe adults (av.)</b>	microns	17.2
<b>Shorn fibre diameter - wether adults (av.)</b>	microns	n/a
<b>Shorn fibre diameter - lambs (av.)</b>	microns	n/a
<b>Meat sold - total (sum)</b>	kg LW/ha	30
<b>Meat sold - young stock (sum)</b>	kg LW/ha	23
<b>Wthr/ram Lambs Sale wt (av.)</b>	kg	26.5
<b>Ewe Lambs Sale wt (av.)</b>	kg	23.6
<b>Supplement fed/area (New Production Feeding rule) (sum)</b>	tonnes/ha	0.024
<b>Supplement fed/area (Maintenance - main flock) (sum)</b>	tonnes/ha	0.013
<b>Supplement fed/area (Maintenance - young (wnr) stock) (sum)</b>	tonnes/ha	0.002

### Gross margin

Long term average gross margin. For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

Farm System		All flocks of Ewes @ Trevenna Low Prod
<b>Net wool income - main flock</b>	\$/ha	1
<b>Net wool income - young stock</b>	\$/ha	0
<b>Sale income - young stock</b>	\$/ha	28

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Sale income - cast-for-age	\$/ha	11
Sale income - sold at foot	\$/ha	0
<b>TOTAL INCOME</b>	\$/ha	40
Maintenance supplement	\$/ha	3
Production supplement	\$/ha	6
Shearing costs	\$/ha	4
Animal husbandry	\$/ha	5
Replacements purchased	\$/ha	28
Rams purchased	\$/ha	4
Sale costs	\$/ha	2
Pasture costs	\$/ha	0
<b>TOTAL EXPENSES</b>	\$/ha	52
<b>GROSS MARGIN</b>	\$/ha	-13

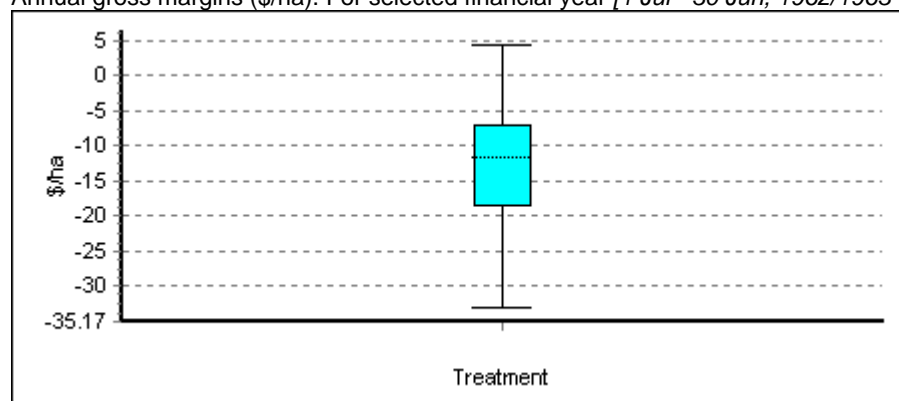

### Variability of Gross Margin

Long term standard deviation of the annual gross margin [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

<b>Farm System</b>	All flocks of Ewes @ Trevena Low Prod	
<b>Total income/ha</b>	\$/ha	5.30
<b>Total expense/ha</b>	\$/ha	9.09
<b>Gross margin/ha</b>	\$/ha	8.64

### Boxplot of gross margins

Annual gross margins (\$/ha). For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

### Interpretation of boxplot

The box shows the middle 50% of values (the interquartile range). The horizontal line inside the box is the median. The lines extending above and below the box (whiskers) show the upper and lower quartiles (25% of values). Beyond the whiskers, outlying values are shown by dots and extreme values are shown by asterisks. "Outlying values" lie more than 1.5 times the interquartile range beyond the upper and lower quartiles. "Extreme values" lie more than 3.0 times the interquartile range beyond the upper and lower quartiles.

### Cumulative distribution of annual gross margins

The probability (on the vertical axis) of exceeding the gross margin value shown on the horizontal axis. For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Cumulative distribution of total supplement fed to whole enterprise

The probability (on the vertical axis) of the total supplement fed in any year exceeding the value shown on the horizontal axis (kg/head). For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

### Cumulative distribution of live weight at sale of wether and ewe lambs (including fleece)

The probability (on the vertical axis) of the live weight at sale in any year exceeding the value shown on the horizontal axis (kg/head, including fleece). For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

### Cumulative distribution of total supplement intake of sheep in main flock and young stock

The probability (on the vertical axis) of the total supplement intake in any year exceeding the value shown on the horizontal axis (kg/head). For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Cumulative distribution of the average fleece fibre diameter of mature sheep

The probability (on the vertical axis) of the fleece fibre diameter in any year exceeding the value shown on the horizontal axis (micron) [1 Jan - 31 Dec, 1962-2010]

### Cumulative distribution of the average fleece fibre diameter of 1-2 year old sheep in the main flock

The probability (on the vertical axis) of the fleece fibre diameter in any year exceeding the value shown on the horizontal axis (micron) [1 Jan - 31 Dec, 1962-2010]

## Sustainability

### Pasture production and water balance

Long term average pasture productivity [1 Jan - 31 Dec, 1962-2010]

<b>Farm System</b>	All flocks of Ewes @ Trevenna Low Prod
<b>Pasture growth (P1)</b>	kg/ha 4040

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Pasture growth (P2)	kg/ha	3634
Pasture growth (P3)	kg/ha	3369
Yearly Rainfall	mm	766
Actual evapotranspiration (P1)	mm	700
Actual evapotranspiration (P2)	mm	696
Actual evapotranspiration (P3)	mm	699
Actual evapotranspiration (P4)	mm	682
Runoff (P1)	mm	0
Runoff (P2)	mm	0
Runoff (P3)	mm	0
Runoff (P4)	mm	3
Drainage below rooting zone (P1)	mm	66
Drainage below rooting zone (P2)	mm	70
Drainage below rooting zone (P3)	mm	67
Drainage below rooting zone (P4)	mm	81

### Ground cover over years

The ground cover for each paddock over time [1/09/1961 - 21/03/2011]

### Cumulative distribution function for minimum ground cover

The probability (shown on the vertical axis) of the minimum ground cover in a year exceeding the value shown on the horizontal axis [2010]

### Methane production

Long term annual average methane production [1 Jan - 31 Dec, 1962-2010]

Date	Methane production -main flock (sum) (g/head)	Methane production -young sheep (sum) (g/head)
-	8713	2983

### Cumulative distribution function for deep drainage

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

The probability (shown on the vertical axis) of the total amount of soil water draining below the root zone each year exceeding the vertical axis (mm/y) [1 Jan - 31 Dec, 1962-2010]

### Timing of drainage

Long term average monthly rainfall (mm/month) and drainage of water below the root zone (mm/month)

Note: distributions are typically highly skewed [1 Jan - 31 Dec, 1962-2010]

### Farm System description

Initial values of Farm System

#### Farm System

<b>Name</b>	All flocks of Ewes @ Trevenna Low Prod
<b>Enterprise type</b>	Ewe
<b>Tested</b>	Over 1 Sep 1961 to 21 Mar 2011
<b>Passed</b>	No
<b>Pasture parameters</b>	C:\Temp\grassgro 2012-03.prm GrassGro March 2012, last edited 13 Jul 2011 by Andrew Moore
<b>Animal parameters</b>	standard, last edited 09 Feb 2004 by Andrew Moore

#### Property: Trevenna

<b>Number of paddocks</b>	4
<b>Total area</b>	48 ha

#### Weather: Armidale Silo Data

<b>Weather station</b>	Armidale Silo Data (from D:\Documents and Settings\mcpheem\Desktop\GrassGro3\custom.set)
<b>Latitude</b>	30°31'S
<b>Longitude</b>	151°40'E
<b>Data period</b>	1 Jan 1961 to 21 Mar 2011
<b>SILO file</b>	D:\Documents and Settings\mcpheem\My

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

	Documents\GrassGro\weather\armidalesilodata.txt
<b>Wind speed</b>	2.0 m/s

### Livestock: New Livestock

Breed	Small Merino		
Standard reference weight	40.0		kg
Greasy fleece weight	3.60		kg
Fibre diameter	17.0		microns
Fleece yield	70		%
Ram breed	Border Leicester (Mature ram: 84.0 kg)		
Death rate: adults	2.0		%/year
Death rate: weaners	2.0		%/year

### Initial values

	Ewes	Wether Lambs	Wether Weaners	Ewe Weaners	Wether Yearlings	Ewe Yearlings	
Live weight including fleece and conceptus	42.5	20.0	25.4	22.1	46.9	39.5	kg
Greasy fleece weight	0.50	1.11	1.00	0.84	2.07	1.73	kg
Fibre diameter	16.7	17.0	17.0	27.0	17.0	17.0	microns

### Management policy: New Ewe Management policy

Stocking rate	<b>Rate</b> 1.0/ha
Shearing date	<b>Main flock</b> 10 Jul
	<b>Weaners</b> 10 Jul
Replacement rule	<b>Purchase</b> Purchase ewes on 2 Apr at age 18 months, live weight 40 kg and C.S. 3.0
	<b>Cast for age</b> Sell stock aged 6 to 7 years on 1 Apr

### Reproduction rule: New Reproduction rule

First join at	1 years
Mating date	14 Apr
Conception at CS 3	(1) 76% (2) 24% (3) 0%
Birth date	10 Sep
Castration	yes
Weaning date	1 Jan

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

<b>One ram per</b>	50 ewes
<b>Keep rams for</b>	5.0 years
<b>Sell young ewes</b>	Sell 0 year old animals on 31 Mar
<b>Sell young wethers</b>	Sell 0 year old animals on 31 Mar

### Maintenance Feeding rule: New Maintenance Feeding rule

#### Main flock/herd

<b>Mature Females</b>	Feed in paddock, applying the rule: If animal condition falls to 1.5 during 1 Jan to 31 Dec feed to maintain condition of the thinnest animals
<b>Immature Females</b>	Feed in paddock, applying the rule: If animal condition falls to 1.5 during 1 Jan to 31 Dec feed to maintain condition of the thinnest animals
<b>Immature Males</b>	Feed in paddock, applying the rule: If animal condition falls to 1.0 during 1 Jan to 31 Dec feed to maintain condition of the thinnest animals

#### Weaner flock/herd

<b>Weaners</b>	Feed in paddock, applying the rule: If animal condition falls to 1.5 during 1 Jan to 31 Dec feed to maintain condition of the thinnest animals
----------------	---

#### Supplement

##### Supplement: Maize

Ingredient	Maize
<b>Proportion of mix (%)</b>	100
<b>Dry matter content (%)</b>	87
<b>Dry matter digestibility (%)</b>	87
<b>ME:DM (MJ/kg)</b>	14.1
<b>Crude protein (%)</b>	10
<b>Rumen-degradable protein (%)</b>	80

### Production Feeding rule: New Production Feeding rule

**Feeding rule** Fixed amount of 0.60 kg/d to All Stock in Paddock from 1 Sep to 10 Oct

#### Supplement

##### Supplement: Hay/Beans, field

**Description** Need the mix in these

Ingredient	Hay	Beans, field	Overall mix
<b>Proportion of mix (%)</b>	50	50	100
<b>Dry matter content (%)</b>	89	89	89
<b>Dry matter digestibility (%)</b>	64	86	75
<b>ME:DM (MJ/kg)</b>	8.5	13.7	11.1
<b>Crude protein (%)</b>	16	31	23
<b>Rumen-degradable protein (%)</b>	68	91	83

### Pasture rule: New Pasture rule

**Reset on** 1 Mar

#### Grazing rule: Grazing rotation

##### Ewes

From 1 Jan to 31 Jan	31 days in "HC2"
From 1 Feb to 29 Feb	29 days in "HA3"
From 1 Mar to 31 Mar	7 days in "HB3"
From 1 Apr to 31 Aug	153 days in "Winter grazing"
From 1 Sep to 9 Oct	39 days in "HB3"
From 10 Oct to 31 Oct	22 days in "HC2"
From 1 Nov to 30 Nov	30 days in "HA3"
From 1 Dec to 31 Dec	31 days in "HB3"

<b>Ewe Replacement</b>	\$130.00	/head
<b>Rams</b>	\$1000.00	/head
<b>Sheep sales commission</b>	4	%
<b>Sheep sales cost</b>	\$0.00	/head
<b>Pasture cost</b>	\$0.00	/ha
<b>Supplement costs</b>	Hay	\$300.00 /t
	Beans, field	\$250.00 /t
	Maize	\$200.00 /t

### Prices: New Prices

#### Wool prices for ewes

Fleece price	800	c/kg
Av. Fleece Price	5.0	%
Wool commission	7.0	%

#### Ewe sales

Base price	260.0	c/kg
Dressing percentage	43.0	%
Skin price	\$15.00	/head

#### Ewe lamb sales

Base price	450.0	c/kg
Dressing percentage	45.0	%
Skin price	\$15.00	/head

#### Wether lamb sales

Base price	0.0	c/kg
Dressing percentage	0.0	%
Skin price	\$0.00	/head

GrassGro 3.2.5. Build: 23 Aug 2011

## GrassGro High Productivity Landscape

09 Apr 2012 17:06

### Acceptability report - All flocks of Ewes @ Trevenna High Prod

1/09/1961 - 21/03/2011

Mean annual rainfall for years tested

Mean annual rainfall [1 Jan - 31 Dec, 1962-2010]

Date	Rainfall
	(sum) (mm)
-	766

Annual rainfall by years

# Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Total annual rainfall [1/09/1961 - 21/03/2011]

## Production over years

Pasture composition by years - Paddock 1

Green available herbage by species [1/09/1961 - 21/03/2011]

Pasture composition by years - Paddock 2

Green available herbage by species [1/09/1961 - 21/03/2011]

Pasture composition by years - Paddock 3

Green available herbage by species [1/09/1961 - 21/03/2011]

**Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

Pasture availability by years - Paddock 1  
Available green and (dead + litter) herbage [1/09/1961 - 21/03/2011]

Pasture availability by years - Paddock 2  
Available green and (dead + litter) herbage [1/09/1961 - 21/03/2011]

Pasture availability by years - Paddock 3  
Available green and (dead + litter) herbage [1/09/1961 - 21/03/2011]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Numbers of sheep in the main flock

Number of animals present (head) [1/09/1961 - 21/03/2011]

### Numbers of young sheep

Number of animals present (head) [1/09/1961 - 21/03/2011]

### Lamb mortality

Number of lambs per ewe and the mortality rate at birth [8 Sep - 12 Sep, 1961-2010]

**Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

Live weight of female sheep in the main flock  
Live weight of each class (kg/head) [1/09/1961 - 21/03/2011]

Live weight of young sheep  
Live weight (kg/head) [1/09/1961 - 21/03/2011]

Fleece weight shorn each year for sheep in the main flock  
Clean fleece weight shorn (kg/head) [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Fleece weight shorn each year for young sheep  
Clean fleece weight shorn (kg/head) [9 Jul - 10 Jul, 1962-2010]

Average annual wool production of age classes in the main flock

Long term average annual clean fleece weight (kg/head) and fleece fibre diameter (micron) [1 Jan - 31 Dec, 1962-2010]

Date	CFW -main flock						Fleece fibre diameter				
	Female weaners (max) (kg/head)	Female 1-2 y.o. (max) (kg/head)	Female mature (max) (kg/head)	Male weaners (max) (kg/head)	Male 1-2 y.o. (max) (kg/head)	Male mature (max) (kg/head)	Female weaners (av.) (microns)	Female 1-2 y.o. (av.) (microns)	Female mature (av.) (microns)	Male weaners (av.) (microns)	Male 1-2 y.o. (av.) (microns)
-	n/a	2.71	2.86	n/a	n/a	n/a	n/a	17.2	17.4	n/a	n/a

Average wool production of young sheep

Long term average clean fleece weight (kg/head) and fleece fibre diameter (micron) [9 Jul - 10 Jul, 1962-2010]

Date	CFW -young sheep					Fleece fibre diameter				
	Unweaned (max) (kg/head)	Male weaners (max) (kg/head)	Male yearlings (max) (kg/head)	Female weaners (max) (kg/head)	Female yearlings (max) (kg/head)	Unweaned (av.) (microns)	Male weaners (av.) (microns)	Male yearlings (av.) (microns)	Female weaners (av.) (microns)	Female yearlings (av.) (microns)
-	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a

Supplement intake of sheep in the main flock

Total monthly supplement intake (kg DM/head) [1/09/1961 - 21/03/2011]

# Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

## Supplement intake of all young sheep

Total monthly supplement intake for all young sheep (kg DM/head) [1/09/1961 - 21/03/2011]

## Variability of the whole farm system

### Distribution of annual rainfall

The probability (shown on the vertical axis) of annual rainfall exceeding the value shown on the horizontal axis (mm) [1 Jan - 31 Dec, 1962-2010]

### Distribution of growing season rainfall

The probability of rainfall between 1 Apr and 31 Oct exceeding the value shown on the horizontal axis (mm) [1 Apr - 31 Oct, 1962-2010]

# Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Monthly rainfall  
Percentiles for monthly rainfall [1 Jan - 31 Dec, 1962-2010]

Temperature  
Long term average of monthly average maximum and minimum air temperature [1 Jan - 31 Dec, 1962-2010]

Pasture supply - green - Paddock 1  
Percentiles for available green herbage [1 Jan - 31 Dec, 1962-2010]

**Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

Pasture supply - green - Paddock 2  
Percentiles for available green herbage [1 Jan - 31 Dec, 1962-2010]

Pasture supply - green - Paddock 3  
Percentiles for available green herbage [1 Jan - 31 Dec, 1962-2010]

Average pasture composition - Paddock 1  
Long term average green available herbage by species [1 Jan - 31 Dec, 1962-2010]

**Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

Average pasture composition - Paddock 2

Long term average green available herbage by species [1 Jan - 31 Dec, 1962-2010]

Average pasture composition - Paddock 3

Long term average green available herbage by species [1 Jan - 31 Dec, 1962-2010]

Variability in live weight of mature female sheep in the main flock  
 Percentiles for live weight, including fleece (kg/head) [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Variability in live weight of ewe lambs

Percentiles for live weight, including fleece (kg/head) [1 Jan - 31 Dec, 1962-2010]

### Variability in live weight of wether lambs

Percentiles for live weight, including fleece (kg/head) [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Variability in body condition of mature female sheep in the main flock  
Percentiles for body condition score [1 Jan - 31 Dec, 1962-2010]

Variability in body condition of ewe lambs  
Percentiles for body condition score [1 Jan - 31 Dec, 1962-2010]

Variability in body condition of wether lambs  
Percentiles for body condition score [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Variability in fibre diameter of mature female sheep in the main flock  
Percentiles for fibre diameter (micron) [1 Jan - 31 Dec, 1962-2010]

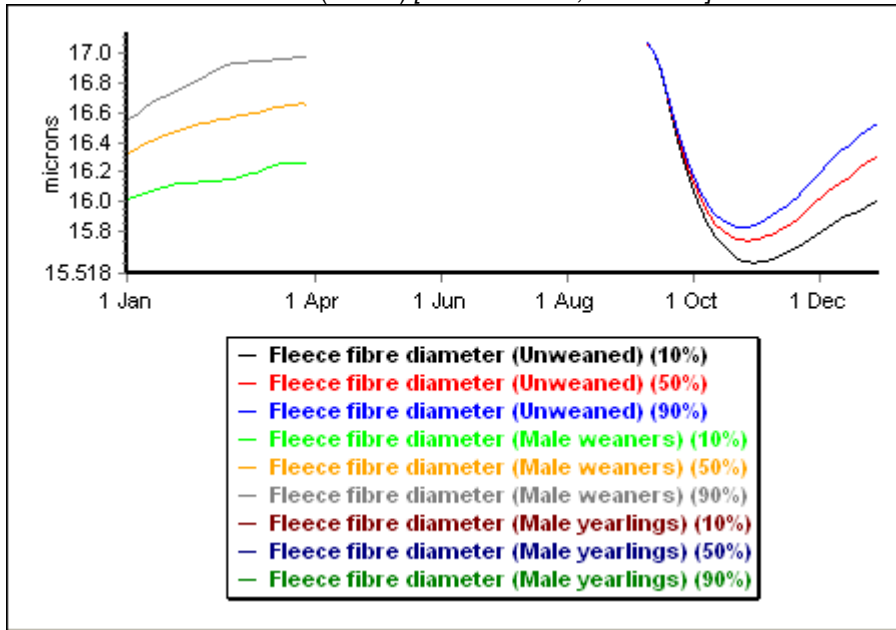

Variability in fibre diameter of 1-2 year old sheep in the main flock  
Percentiles for fibre diameter (micron) [1 Jan - 31 Dec, 1962-2010]

# Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Variability in fibre diameter of young wethers (unweaned and weaned)  
 Percentiles for fibre diameter (micron) [1 Jan - 31 Dec, 1962-2010]

Lambs per ewe  
 Percentiles for lambs per ewe [1 Jan - 31 Dec, 1962-2010]

Variability in intake of maintenance and production supplement of the main flock  
 Percentiles for daily supplement intake (kg DM/head/d) [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Variability in intake of maintenance and production supplement of young sheep  
 Percentiles for total daily supplement intake of young sheep (kg DM/head/d) [1 Jan - 31 Dec, 1962-2010]

Variability in average daily gain (ADG) of wether lambs  
 Percentiles for average daily live weight gain -not fleece (kg/head/d) [1 Jan - 31 Dec, 1962-2010]

## Pasture quality

Average quality of all herbage in each paddock  
 Long term average pasture dry matter digestibility (%) [1 Jan - 31 Dec, 1962-2010]

**Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

Average quality of green herbage for each paddock  
Long term average pasture dry matter digestibility (%) [1 Jan - 31 Dec, 1962-2010]

Average quality of dead herbage and litter for each paddock  
Long term average pasture dry matter digestibility (%) [1 Jan - 31 Dec, 1962-2010]

Variability in pasture growth rate - Paddock 1  
Percentiles for average weekly pasture growth rate (kg DM/ha/d) [1 Jan - 31 Dec, 1962-2010]

**Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

Variability in pasture growth rate - Paddock 2  
Percentiles for average weekly pasture growth rate (kg DM/ha/d) [1 Jan - 31 Dec, 1962-2010]

Variability in pasture growth rate - Paddock 3  
Percentiles for average weekly pasture growth rate (kg DM/ha/d) [1 Jan - 31 Dec, 1962-2010]

Pasture growth rates for each paddock  
Long term average pasture growth rates [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Table of average monthly pasture and sheep growth rates

Long term average pasture and sheep growth rates, averaged over each month [1 Jan - 31 Dec, 1962-2010]

Date	Pasture growth	Pasture growth	Pasture growth	Weight change (Unweaned)	Weight change (Male weaners)	Weight change (Female weaners)	Weight change (Main mob)					
	P1 (av.) (kg/ha/d)	P2 (av.) (kg/ha/d)	P3 (av.) (kg/ha/d)	(av.) (kg/d)	(av.) (kg/d)	(av.) (kg/d)	Female weaners (av.) (kg/d)	Female 1-2 y.o. (av.) (kg/d)	Female mature (av.) (kg/d)	Male weaners (av.) (kg/d)	Male 1-2 y.o. (av.) (kg/d)	Male mature (av.) (kg/d)

### Feed budget

Long term average daily pasture growth and intake of pasture by the whole enterprise (kg DM/ha/d) [1 Jan - 31 Dec, 1962-2010]

### Pasture utilization rate

The long term average amount of pasture consumed by all stock as a proportion of the amount of pasture grown over the period tested (%) [21 Mar - 21 Mar, 2011-2011]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Date	Utilization rate
	(%)
21 Mar	12

### Economics

#### Production summary

Long term average pasture and sheep production. For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

Farm System		All flocks of Ewes @ Trevenna High Prod
<b>Total annual pasture yield (NPP) (sum)</b>	kg/ha	8026
<b>Dry sheep equivalents (av.)</b>	dse/ha	3.2
<b>Wool cut - total flock (sum)</b>	kg CFW/ha	6
<b>Wool cut - lambs (sum)</b>	kg CFW/ha	0
<b>Shorn fibre diameter - ewe adults (av.)</b>	microns	17.4
<b>Shorn fibre diameter - wether adults (av.)</b>	microns	n/a
<b>Shorn fibre diameter - lambs (av.)</b>	microns	n/a
<b>Meat sold - total (sum)</b>	kg LW/ha	76
<b>Meat sold - young stock (sum)</b>	kg LW/ha	59
<b>Wthr/ram Lambs Sale wt (av.)</b>	kg	31.0
<b>Ewe Lambs Sale wt (av.)</b>	kg	27.8
<b>Supplement fed/area (New Production Feeding rule) (sum)</b>	tonnes/ha	0.047
<b>Supplement fed/area (Maintenance - main flock) (sum)</b>	tonnes/ha	0.001
<b>Supplement fed/area (Maintenance - young (wnr) stock) (sum)</b>	tonnes/ha	0.000

#### Gross margin

Long term average gross margin. For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

Farm System		All flocks of Ewes @ Trevenna High Prod
<b>Net wool income - main flock</b>	\$/ha	2
<b>Net wool income - young stock</b>	\$/ha	0
<b>Sale income - young stock</b>	\$/ha	71
<b>Sale income - cast-for-age</b>	\$/ha	24
<b>Sale income - sold at foot</b>	\$/ha	0
<b>TOTAL INCOME</b>	\$/ha	97
<b>Maintenance supplement</b>	\$/ha	0
<b>Production supplement</b>	\$/ha	13
<b>Shearing costs</b>	\$/ha	9
<b>Animal husbandry</b>	\$/ha	10
<b>Replacements purchased</b>	\$/ha	55
<b>Rams purchased</b>	\$/ha	8
<b>Sale costs</b>	\$/ha	4
<b>Pasture costs</b>	\$/ha	0
<b>TOTAL EXPENSES</b>	\$/ha	99
<b>GROSS MARGIN</b>	\$/ha	-2

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Variability of Gross Margin

Long term standard deviation of the annual gross margin [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

<b>Farm System</b>	All flocks of Ewes @ Trevenna High Prod	
<b>Total income/ha</b>	\$/ha	7.69
<b>Total expense/ha</b>	\$/ha	8.66
<b>Gross margin/ha</b>	\$/ha	8.58

### Boxplot of gross margins

Annual gross margins (\$/ha). For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

### Interpretation of boxplot

The box shows the middle 50% of values (the interquartile range). The horizontal line inside the box is the median. The lines extending above and below the box (whiskers) show the upper and lower quartiles (25% of values). Beyond the whiskers, outlying values are shown by dots and extreme values are shown by asterisks. "Outlying values" lie more than 1.5 times the interquartile range beyond the upper and lower quartiles. "Extreme values" lie more than 3.0 times the interquartile range beyond the upper and lower quartiles.

### Cumulative distribution of annual gross margins

The probability (on the vertical axis) of exceeding the gross margin value shown on the horizontal axis. For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

### Cumulative distribution of total supplement fed to whole enterprise

The probability (on the vertical axis) of the total supplement fed in any year exceeding the value shown on the horizontal axis (kg/head). For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Cumulative distribution of live weight at sale of wether and ewe lambs (including fleece)  
The probability (on the vertical axis) of the live weight at sale in any year exceeding the value shown on the horizontal axis (kg/head, including fleece). For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

Cumulative distribution of total supplement intake of sheep in main flock and young stock  
The probability (on the vertical axis) of the total supplement intake in any year exceeding the value shown on the horizontal axis (kg/head). For selected financial year [1 Jul - 30 Jun, 1962/1963 - 2009/2010]

Cumulative distribution of the average fleece fibre diameter of mature sheep  
The probability (on the vertical axis) of the fleece fibre diameter in any year exceeding the value shown on the horizontal axis (micron) [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Cumulative distribution of the average fleece fibre diameter of 1-2 year old sheep in the main flock

The probability (on the vertical axis) of the fleece fibre diameter in any year exceeding the value shown on the horizontal axis (micron) [1 Jan - 31 Dec, 1962-2010]

## Sustainability

### Pasture production and water balance

Long term average pasture productivity [1 Jan - 31 Dec, 1962-2010]

Farm System	All flocks of Ewes @ Trevenna High Prod	
Pasture growth (P1)	kg/ha	8978
Pasture growth (P2)	kg/ha	8491
Pasture growth (P3)	kg/ha	8183
Yearly Rainfall	mm	766
Actual evapotranspiration (P1)	mm	709
Actual evapotranspiration (P2)	mm	708
Actual evapotranspiration (P3)	mm	708
Actual evapotranspiration (P4)	mm	682
Runoff (P1)	mm	0
Runoff (P2)	mm	0
Runoff (P3)	mm	0
Runoff (P4)	mm	3
Drainage below rooting zone (P1)	mm	58
Drainage below rooting zone (P2)	mm	58
Drainage below rooting zone (P3)	mm	59
Drainage below rooting zone (P4)	mm	82

# Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

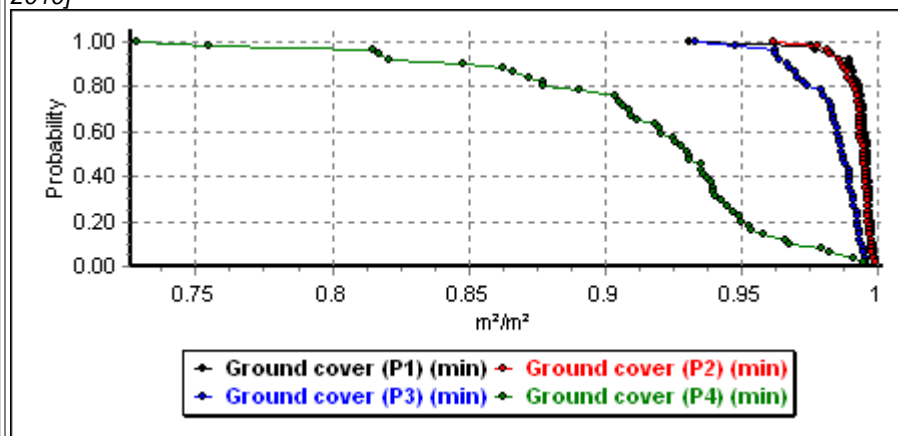

## Ground cover over years

The ground cover for each paddock over time [1/09/1961 - 21/03/2011]

## Cumulative distribution function for minimum ground cover

The probability (shown on the vertical axis) of the minimum ground cover in a year exceeding the value shown on the horizontal axis [2010]

## Methane production

Long term annual average methane production [1 Jan - 31 Dec, 1962-2010]

Date	Methane production -main flock (sum) (g/head)	Methane production -young sheep (sum) (g/head)
-	8957	3340

## Cumulative distribution function for deep drainage

The probability (shown on the vertical axis) of the total amount of soil water draining below the root zone each year exceeding the value shown on the horizontal axis (mm/y) [1 Jan - 31 Dec, 1962-2010]

## Timing of drainage

Long term average monthly rainfall (mm/month) and drainage of water below the root zone (mm/month)

Note: distributions are typically highly skewed [1 Jan - 31 Dec, 1962-2010]

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

### Farm System description

Initial values of Farm System

#### Farm System

<b>Name</b>	All flocks of Ewes @ Trevenna High Prod
<b>Enterprise type</b>	Ewe
<b>Tested</b>	Over 1 Sep 1961 to 21 Mar 2011
<b>Passed</b>	No
<b>Pasture parameters</b>	C:\Temp\grassgro 2012-03.prm GrassGro March 2012, last edited 13 Jul 2011 by Andrew Moore
<b>Animal parameters</b>	standard, last edited 09 Feb 2004 by Andrew Moore

#### Property: Trevenna

<b>Number of paddocks</b>	4
<b>Total area</b>	48 ha

#### Weather: Armidale Silo Data

<b>Weather station</b>	Armidale Silo Data (from D:\Documents and Settings\mcpheem\Desktop\GrassGro3\custom.set)
<b>Latitude</b>	30°31'S
<b>Longitude</b>	151°40'E
<b>Data period</b>	1 Jan 1961 to 21 Mar 2011
<b>SILO file</b>	D:\Documents and Settings\mcpheem\My Documents\GrassGro\weather\armidalesilodata.txt
<b>Wind speed</b>	2.0 m/s
<b>Last edited</b>	20 Mar 2012

#### Paddock: FA1

<b>Area</b>	6.4 ha
<b>Steepness</b>	Level
<b>Fertility</b>	0.90
<b>Reduce wind to</b>	100%

#### Soil: New Soil

<b>Soil albedo</b>	0.17
<b>Soil evaporation</b>	3.3 mm/d <sup>1/2</sup>
<b>SCS runoff curve no.</b>	Using default

#### Topsoil Subsoil

<b>Cumulative depth (mm)</b>	200	900
------------------------------	-----	-----

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

Field capacity (m <sup>3</sup> /m <sup>3</sup> )	0.27	0.30
Wilting point (m <sup>3</sup> /m <sup>3</sup> )	0.13	0.20
Bulk density (Mg/m <sup>3</sup> )	1.20	1.50
Saturated conductivity (mm/hr)	30.00	10.00
Initial water (m <sup>3</sup> /m <sup>3</sup> )	0.13	0.20

### Pasture: Flatss Landscape Within A

Population	Bothriochloa (beta)	Perennial Ryegrass	White Clover	Annual Ryegrass
Phenology	Vegetative (900)	Reproductive (200)	Vegetative (900)	Vegetative (650)

### Management policy: New Ewe Management policy

Stocking rate	Rate	2.0/ha
Shearing date	Main flock	10 Jul
	Weaners	10 Jul
Replacement rule	Purchase	Purchase ewes on 2 Apr at age 18 months, live weight 40 kg and C.S. 3.0
	Cast for age	Sell stock aged 6 to 7 years on 1 Apr

### Reproduction rule: New Reproduction rule

First join at	1 years
Mating date	14 Apr
Conception at CS 3	(1) 63% (2) 37% (3) 0%
Birth date	10 Sep
Castration	yes
Weaning date	1 Jan
One ram per	50 ewes
Keep rams for	5.0 years
Sell young ewes	Sell 0 year old animals on 31 Mar
Sell young wethers	Sell 0 year old animals on 31 Mar

### Maintenance Feeding rule: New Maintenance Feeding rule

Main flock/herd	
Mature Females	Feed in paddock, applying the rule: If animal condition falls to 1.5 during 1 Jan to 31 Dec feed to maintain condition of the thinnest animals
Immature Females	Feed in paddock, applying the rule: If animal condition falls to 1.5 during 1 Jan to 31 Dec feed to maintain condition of the thinnest animals

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

**Immature Males** Feed in paddock, applying the rule:  
If animal condition falls to 1.0 during 1 Jan to 31 Dec feed to maintain condition of the thinnest animals

### Weaner flock/herd

**Weaners** Feed in paddock, applying the rule:  
If animal condition falls to 1.5 during 1 Jan to 31 Dec feed to maintain condition of the thinnest animals

Supplement	Supplement: Maize	
	Ingredient	Maize
	Proportion of mix (%)	100
	Dry matter content (%)	87
	Dry matter digestibility (%)	87
	ME:DM (MJ/kg)	14.1
	Crude protein (%)	10
	Rumen-degradable protein (%)	80

### Production Feeding rule: New Production Feeding rule

**Feeding rule** Fixed amount of 0.60 kg/d to All Stock in Paddock from 1 Sep to 10 Oct

Supplement	Supplement: Hay/Beans, field			
	Description	Need the mix in these		
	Ingredient	Hay	Beans, field	Overall mix

# Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

The screenshot shows the 'Simulation statistics' window with the 'GHG' tab selected. The 'Paddock' section contains a table of carbon fluxes and a note about stock values. The 'Summary dates' section shows the simulation period from 1/09/2010 to 21/03/2011. The 'CO2e parameters' section shows Methane at 21.0 and Nitrous Oxide at 310.0. A 'Copy' button is visible below the parameters, and 'Close' and 'Help' buttons are at the bottom right.

		CO2e, t/ha/y
Pasture C fix: tC/ha/year	6.92	25.37
Soil C fix: tC/ha/year	9.36	34.34
Soil C resp: tC/ha/year	10.39	38.10
N2O emission: kgN/ha/year	1.15	0.56
Stock CO2 resp: tC/ha/year	0.70	2.58
Stock CH4 resp: tC/ha/year	0.040	1.11
Net balance: t CO2e / ha / year		-16.98

Stock values are only shown for the time that the stock were on this paddock.

The first column of data have the units listed in the description on the left.  
 The second column is the conversion to CO2 equivalents converted to t/ha/year as indicated.  
 If the net balance is positive, it shows the CO2 equivalents being incorporated in the system, if it is negative then there is a loss from the system.

Note that there will be some carbon inputs to the system through supplementary feeding. This means that the system is not 'closed'.

### SGS Low Productivity Landscape Paddock HB3, Flock 1

Note: only 1 paddock and 1 flock to illustrate the simulation.

# Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

The screenshot shows a software window titled "Simulation statistics" with a blue title bar. The window contains several tabs: "Water", "EA", "Nutrients", "Monthly events", "Pasture and animal" (which is selected), "Cut", and "GHG".

Under the "Pasture and animal" tab, there is a section labeled "Paddock" containing a table of statistics:

Pasture intake: t/ha/year	1.85
% live intake	96.93
% dead intake	3.07
Total cut yield: t/ha/year	0.00
Concentrate intake: t/ha/year	0.00
Forage intake: t/ha/year	0.00
Greasy fleece sheared: kg / sheep	2.55

To the right of the table, there are two explanatory text blocks:

Feed inputs are only shown for the time that the stock were on this paddock.

Total pasture growth excludes any losses to senescence and so is generally greater than measured growth rates

At the bottom left of the main content area, it says "Dry weights have units t/ha".

On the right side of the window, there is a "Summary dates" section with a "Year:" dropdown menu set to "50" and a date range of "1/09/2010 to 21/03/2011".

At the bottom right, there are three buttons: "Copy", "Close", and "Help".

# Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

## FarmGas Calculations for Low Productivity Landscape

**FarmGAS Scenario - Setup ("Landing Page")**

This is the 'test-bed' version of the FarmGAS Scenario Tool (Version 1.2, February 2012). It was developed to provide a template for construction of a Web-based version of the Scenario Tool which is located on the website of the Australian Farm Institute ( www.farminstitute.org.au ). Advice on, and approval for, the use of this spreadsheet should be obtained from the Australian Farm Institute.

The development of the Scenario Tool is part of a project undertaken by the Institute and Meat & Livestock Australia, under the Australian Government's Reducing emissions from livestock R&D Program which forms part of the Australia's Farming Future: Climate Change Research Program.

A detailed outline of this spreadsheet model and instructions on its use are provided in the FarmGAS Scenario Tool User Guide (Spreadsheet) which can be obtained from the Australian Farm Institute.

**SCENARIO NAME and FARM LOCATION**

Farm Name:   
 Scenario:  (Name of the scenario)      Scenario created on:

Irrigated pastures	0.0			0.0%	0.0	0.0	0%
<b>Total area of Pastures</b>	<b>17.0</b>						

Total area legume:       Area burnt:

Note: % legume can include mixed pasture (eg 50% lucerne, 70% native grasses)

from:		Feedlot	Piggery
Tonnes Waste (organic fertiliser):		0.0	0.0
Emissions (tonnes CO <sub>2</sub> -e):		0.0	0.0
Emissions (tonnes CO <sub>2</sub> -e) / tonne waste =		0.00	0.00

Do you want to include estimated GHG emissions from legume-based (i.e. Nitrogen-fixing) Pastures?  YES

Calculation of GHG emissions from the legume pastures will require an estimate of the annual amount of residual pasture 'dry matter' (DM tonnes/ha) that is NOT:  
 a) eaten by stock      Dryland residual pasture      DM tonnes/ha:       % legume content:       Total Residual (legume) Dry Matter:  tonnes/DM/year  
 b) baled/silage'd or      Irrigated residual pasture      DM tonnes/ha:       % legume content:       Total Residual (legume) Dry Matter:  tonnes/DM/year  
 c) burnt.      % legume content is based on % value entered above

**Savanna areas:** (QLD & NT territory only)      hectares      Area burnt each year

Savanna grasslands	<input type="text" value="#####"/>	<input type="text" value="500.0"/>
Savanna woodland	<input type="text" value="#####"/>	<input type="text" value="100.0"/>

The definition of 'savanna' is "...tropical and sub-tropical formations with continuous grass cover occasionally interrupted by trees and shrubs". This includes monsoonal through to semi-arid grasslands.

## FarmGas Calculations for High Productivity Landscape

**FarmGAS Scenario - Setup ("Landing Page")** This is the version of the FarmGAS model that is consistent with the model on the Australian Farm Institute website - Version 1.2 - February 2012.

This is the 'test-bed' version of the FarmGAS Scenario Tool (Version 1.2, February 2012). It was developed to provide a template for construction of a Web-based version of the Scenario Tool which is located on the website of the Australian Farm Institute ( www.farminstitute.org.au ). Advice on, and approval for, the use of this spreadsheet should be obtained from the Australian Farm Institute.

The development of the Scenario Tool is part of a project undertaken by the Institute and Meat & Livestock Australia, under the Australian Government's Reducing emissions from livestock R&D Program which forms part of the Australia's Farming Future, Climate Change Research Program.

A detailed outline of this spreadsheet model and instructions on its use are provided in the FarmGAS Scenario Tool User Guide (Spreadsheet) which can be obtained from the Australian Farm Institute.

**Abstract:** Sheep production is the major contributor to the agricultural economy of the Northern Tablelands of New South Wales. In 1996/97 \$109.1 million was derived from sheep production. There is a pressing need for agricultural industries to reduce their carbon footprint and global warming is a major concern. This study has simulated a sheep production system of a 36 ha research station called 'Trevenna' located at the University of New England, Armidale (30° 30'S 151° 40' E). The 'Trevenna' site has been set up as a demonstration site for producers, advisers, students, and researchers to gain insight into how to estimate and measure livestock enteric methane emissions.

The Sustainable Grazing Systems (SGS) model was used to simulate, over 50 years, pasture growth on the 'Trevenna' demonstration site. Simulations contrasted the impacts of a 2°C change in temperature on herbage mass (t/ha) and pasture growth rate (kg C/ha/day). A validation check indicated that the predicted values from 1<sup>st</sup> Sep 2010 to 30<sup>th</sup> March 2011 fell within 10% of the observed values.

There was no effect of the 2°C increase in temperature on green herbage mass ( $P > 0.05$ ) but a significant difference for dead herbage mass and pasture growth rate ( $P < 0.05$ ). The increase in dead herbage mass is discussed.

A significant effect of temperature on botanical composition ( $P < 0.05$ ) was found with an increase in C4 native grasses (e.g. kangaroo grass, red grass, and wire grass) at the expense of other pasture species present in the sward. The impact of a 2°C increase in temperature reduced the number of frosts (defined as mornings below 2°C) and number of severe frosts (defined as mornings below 0°C).

In conclusion, a 2°C increase in temperature on the Northern Tablelands of New South Wales can be expected to increase pasture growth, particularly of C4 species, so supporting an increase in herbage mass.

**Keywords:** Climate change, decision support system, herbage mass, senescence

## **1. INTRODUCTION**

A large proportion of the Northern Tablelands in New South Wales is grazed for sheep production, particularly fine-wool flocks. Within these grazing systems the majority of pastures are a combination of introduced, improved, and native species. The total value of agricultural production on the Northern Tablelands in 1996/97 was estimated at \$217.8 million: 50.1% derived from sheep production; 41.7% derived from wool production; and 8.4% from prime lamb production (Alford et al., 2003). Herbage mass (kg DM/ha) is a key determinate of stocking rate that an enterprise can carry and therefore the amount of animal product that can be generated. Climate variability is a major issue confronting agriculture. There is a pressing need for agricultural industries to reduce their carbon footprint. Agricultural emissions (methane (CH<sub>4</sub>) and nitrous oxide (N<sub>2</sub>O)) comprise 16% of Australia's total emissions, and livestock emissions (enteric fermentation and manure management) contribute 69% of agricultural emissions (Department of Climate Change and Energy Efficiency 2010). Therefore, it is of great interest to determine the effects of a change in temperature on pasture production. Several studies have estimated the effects of an increase in minimum and maximum temperature on pasture production (Thornley and Cannell, 1997, Cullen et al., 2009). However, no specific studies on the Northern Tablelands have been undertaken. This study has simulated a sheep production system on a 36 ha research station called 'Trevenna' located at the University of New England, Armidale (30° 30'S 151° 40' E) using the Sustainable Grazing Systems (SGS) model (Johnson et al., 2003).

The objective of this study was to evaluate the impact of a 2°C increase in temperature on pasture growth within a sheep production enterprise on the Northern Tablelands of New South Wales, Australia.

## **2. MATERIAL AND METHODS**

### **2.1 Trevenna Demonstration Site**

The Trevenna demonstration site, located at the University of New England, on the Northern Tablelands of New South Wales (30° 30'S 151° 40' E) comprises 36 ha, split between high and low productivity systems. An overview of the site has been described by McPhee et al. (2010). The 'Trevenna' demonstration site has been subdivided into 18 paddocks: 9 allocated for high productivity improved pastures and 9 allocated for low productivity predominately native pastures. The paddocks averaged 2ha ranging from 1.8-2.2 ha. Each landscape was classified into classes (A, B and C) based on an EM38 electromagnetic induction survey. Within each class 3 paddocks were allocated. There were 6 flocks: 3 high and 3 low productivity flocks. Flocks were rotationally grazed through 3 paddocks so that each flock had a turn in each landscape class (A, B and C). The high productivity flocks were stocked at 6.7 DSE/ha (i.e. 32 ewes and single lambs rotationally grazing 6ha) and the low productivity flocks were stocked at 3.7 DSE/ha (i.e. 16 ewes and single lambs rotationally grazing 6ha).

### **2.2 Data Collection**

Data has been collected to feed into decision support systems to estimate the amount of methane produced. The data collected will also be used as inputs to

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

greenhouse inventory calculators (e.g. FarmGas (2010)). The measurements taken include:

- Soil moisture measurements taken on a weekly basis. Measurements were taken using a Diviner moisture probe (Sentek Technologies, Sydney). The moisture probe used was a capacitance probe that uses the electrical conductivity of a soil to determine the moisture content (Thomas, 1966). The access tubes were located within one paddock of each land class within each landscape. The measurements were taken in 10cm increments to a depth of 50cm.
- Herbage mass measurements were undertaken on a monthly basis when the animals were rotated between paddocks. Pre and post grazing measurements were undertaken using the median quadrat technique (Bell, 2007). A scan of each quadrat was taken using a Crop Circle (Holland Scientific equipment model ACS210) scanner. The data from the observed values and the scans have been used to develop a Normalised Difference Vegetation Index (Trotter et al., 2010)
- Botanical compositions were conducted 4 times per year, once per season using the method described by Tothill et al. (1992).
- Lambs were weighed on a monthly basis, when mobs were rotated between paddocks. These monthly lamb weights were recorded using their National Livestock Identification System Radio Frequency Identification tag. Condition score, fleece weights, and quality of fleece were also recorded.

### 2.3 Simulation

The SGS model (Johnson, 2003) was used to perform a 50 year simulation of high and low productivity sheep production systems. The soil parameters in the SGS model were stabilised over a 10 year period from 1960 to 1970 before a full 50 year simulation from 1960-2010 was conducted. Each of the 2 landscapes was modelled separately for 3 flocks on each landscape that was rotational grazed across 3 paddocks using the information recorded from the Trevenna site (McPhee et al., 2010). Data used from the site included: herbage mass, species composition and stocking density. Table 1 reports the input values used in the simulations.

Within the SGS model supplementary feeding was established to begin feeding when ewes dropped below 40kg liveweight. Below this weight forage and concentrate supplements were fed at a rate calculated by the model to produce liveweight gains. The implementation of

**Table 1.** Input values used in the SGS model for 'Trevenna'

## **Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)**

supplementary feeding within the SGS model occurred when the pasture quantity and quality was insufficient to maintain liveweight. Actual on-farm supplementary feeding was supplied to ewes as per the UNE animal ethics requirements.

The simulation was run using historical weather data for Armidale Airport Automatic Weather Station, NSW (30.5°S 151.6°E) (BOM, 2011). The initial pasture availability at the beginning of September 2010 was used as the starting herbage mass 1st September, 1960. The botanical composition assessment conducted in September was used as inputs to the SGS model. The soil nutrients and water values were used from the normalised values obtained in the 10 year scenario (1960-1970). Following the simulation the data produced was processed using the Post Processor 3 program. The program specifically developed as part of the SGS project summarising the model output (Anon., 2011). The data was processed to provide monthly summaries of all factors. Following the historical simulation the weather data was combined with the CSIRO Mk 3.5 Model following the A2, medium emissions scenario, using the climate downscaling software tool WeatherMaker (Gordon et al., 2010). The daily weather output file from this program was used as the observed weather values for the SGS model where the minimum and maximum temperatures were increased by 2°C. These weather values were then used with the same initial conditions for the historical weather data (baseline) scenario (i.e. 2 simulations were conducted: (1) baseline; and (2) a 2°C increase in minimum and maximum temperatures of the baseline year).

To ensure accuracy of the model the baseline simulation was run from the 1st September 2010 through to the 31<sup>st</sup> of March 2011. This enabled the predicted values from the simulation to be compared to the observed values of herbage mass, botanical composition, soil moisture and lamb weights.

### **2.4 Statistical Analysis**

The results from the simulation were analysed using the statistical package R (R Development Core Team, 2005). An analysis of variance was performed to compare the differences in herbage mass and pasture growth with a 2°C increase in temperature. No statistical interpretation between landscapes can be made because only 1 year of the experiment has been conducted (i.e. not a replicated study). This study only evaluates the difference between the baseline and the 2°C increase in temperature.

### **3. RESULTS**

Following the 50 year simulation the observed versus predicted values of herbage mass, botanical composition, soil moisture, and lamb weights from 1<sup>st</sup> Sep 2010 to 30<sup>th</sup> March 2011 were found to be consistent and fell within 10% of the observed values, giving confidence in interpretation of modelled impacts on pasture growth over the 50 year time frame

The 50 year simulation showed no statistical difference ( $P > 0.05$ ) between the baseline and 2°C increase in temperature simulations for green herbage mass or total herbage mass, but a significant difference ( $P < 0.05$ ) for dead herbage mass (Table 1). Nevertheless the 2°C increase did increase total herbage mass compared to the baseline climate data (Table 1).

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

**Table 1.** Mean and standard deviation (SD), over 50 year simulation, green, dead and total herbage mass (tDM/ha) and mean gross positive growth rate<sup>1</sup> (kg carbon/ha/day) across sheep enterprises grazing low or high productivity landscapes, in the presence of historical temperatures (Baseline) and 2°C increase in temperature

Landscape	Climate Scenario	Green Herbage Mass (tDM/ha)	SD	Dead Herbage Mass (tDM/ha)	SD	Total Herbage Mass (tDM/ha)	SD	Gross Positive Growth Rate <sup>1</sup> (kg C/ha/day)	SD
Low	Baseline	1.19	0.54	1.20 <sup>a</sup>	0.47	2.39	0.97	18.50 <sup>a</sup>	5.49
Low	2 <sup>o</sup> increase	1.26	0.58	1.37 <sup>b</sup>	0.57	2.63	1.03	20.56 <sup>b</sup>	7.00
High	Baseline	1.64	0.52	0.92 <sup>a</sup>	0.32	2.28	0.75	33.01 <sup>a</sup>	11.91
High	2 <sup>o</sup> increase	1.57	0.67	1.17 <sup>b</sup>	0.41	2.73	1.10	35.56 <sup>b</sup>	13.26

composition the high productivity landscape (Figure 1) was statistically significant ( $P < 0.05$ ) for all pasture species (C3 (e.g., weeping grass and common wheatgrass), C4 (e.g. kangaroo grass, red grass, and wire grass), White Clover, Perennial Rye)

**Figure 1.** Predicted species abundance (%) across 50 year simulation of the high productivity landscape between Baseline

between the baseline and changed scenarios. However for the low productivity landscape (Figure 2) only C4 and Perennial Rye were statistically significant ( $P < 0.05$ ) between the baseline and changed scenarios.

#### 4. DISCUSSION

The higher gross positive growth rate (daily gross photosynthesis + remobilised carbon from senescent tissue) that occurred in the high productivity landscape compared to the low productivity landscape in both climate scenarios may be attributed to the botanical composition. Robinson and Archer (1988) showed that introduced species have a higher growth rate compared to native species. The low productivity landscape class consists predominantly of native pasture species, while the high productivity landscape consists of introduced perennial species (McPhee et al., 2010). The high productivity landscape is more responsive to additional fertility and to water, exhibiting a faster growth rate. The increase in growth rate as a result of a 2°C increase is due to the warmer temperatures experienced and lower frost damage to plants.

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

**Figure 2.** Predicted species abundance (%) across 50 year simulation of the low productivity landscape between Baseline (historical temperatures) and 2°C increase in temperature (Changed).

The herbage mass present is a function of the growth rate and number of animals grazing. The results from this study show that a difference in pasture growth rate occurred when the minimum and maximum temperatures were increased by 2°C and consequently a change in herbage mass. As the stocking rates were unchanged, the pasture consumption was unchanged. A net increase in herbage mass occurred because the stocking rate and consequently intake did not change.

As the temperature increased the number of frosts, (defined as mornings below 2°C) was reduced. The number of severe frosts, (defined as mornings below 0°C) also declined. The lower number of mild and severe frosts therefore increased the growth rate as the low temperature effects are reduced (Ludlow, 1980). This effect is more pronounced in the Spring and Autumn, as the mean minimum temperature during the Northern Tablelands winter is 0.95°C (BOM, 2011). An increase in 2°C results in the temperature remaining below the lower critical temperature of C4 grasses (4°C) (Ivory and Whiteman, 1978). Hence, even in the warmer climate, cold temperatures remain a restriction to pasture growth. A reduction in pasture growth rate on the low productivity landscape may have occurred due to the high proportion of native C4 grasses (Figure 2). A mean increase of 2°C will increase the mean minimum temperature to 2.95 degrees. This is above the lower critical temperature of many temperate introduced species, allowing increased pasture growth rate on the high productivity landscape.

The small increase in green herbage mass on the low productivity scenario in response to an increase in temperature may have occurred because of the reduction in plant death associated with reduction in frosts. This is contrasted with the decrease in green herbage mass that occurs in the high productivity landscape as a result of the 2°C increase (Figure 1). This could have occurred on the low productivity landscape as a result of increased pasture intake and a decrease supplementary feed intake. Gurung et al. (1994) showed that sheep will graze green herbage in preference to dead.

The results from this study show that the increased proportion of C4 grasses that were found to be present as the temperature increased may be attributed to the

## Managing carbon in livestock systems: modelling options for net carbon balance (UNE/I&I NSW)

temperature increase favouring their growth and therefore increasing the C4 herbage mass present in the sward. The magnitude of the increase was similar in both landscapes, approximately doubling in prevalence as the temperature increased. In conclusion a 2°C increase in minimum and maximum temperatures significantly increased pasture growth rate and the species abundance of the C4 grasses present in the sward; with this resulting in part from reduced frost impact on these species in warmer conditions. As stocking rate was not changed in the model, the extra pasture growth at the warmer temperature led to an increased accumulated mass of dead pasture.

### ACKNOWLEDGEMENTS

The authors thank Meat & Livestock Australia and the Australian Government Climate Change Research Program for funding this project and a Cicerone scholarship for an honours student to undertake this project.
